(54) Printing member provided with identification means and method for embedding said means in said member

(57) A printing member (1) such as a printing cylinder, for example an at least partly metal cylinder, or a sleeve to be mounted on a mandrel rotating about its axis, said printing member (1) comprising a body (2)

having a thickness (7). With said member (1) there are associated identification means (10) connectable to recording means (16) arranged to store data related to at least one characteristic of said member (1) or to the use of this latter.

F/I.G. 1

EP 1 559 572 A1

Description

[0001] The present invention relates to a printing member and to a method in accordance with the introduction to the corresponding independent claims.

[0002] The term "printing member" as used in the present document means any member for directly or indirectly transferring information onto a miscellaneous support by flexographic, copper-plate or offset printing. Consequently said term comprises any one of the following elements: a printing cylinder in general such as a steel cylinder, a steel cylinder with chromium plated surface, a steel cylinder with rubber cladding, an aluminium cylinder with anodised or non-anodized surface; a printing sleeve to be mounted, in known manner such as by deformation with compressed air or by other means, on a mandrel (possibly of radially deformable type) rotating about its longitudinal axis, said sleeve being of composite material such as glass fibre, aramid fibre, carbon fibre or combinations of these fibres, said sleeve of fibre or composite material being clad with a polyurethane or rubber layer or presenting a chromium plated covering surface, or being clad with polyester or epoxy resin; a nickel sleeve unclad, or clad with rubber or polyurethane. Said printing member can present print characters or images on its outer surface (characters or images which may be directly formed on it or provided on plates or blocks fixed to said surface in any known manner) to consequently enable direct printing of said characters or images on a suitable support in a flexographic or copper-plate printing machine; alternatively said printing member can be used as a roller in an intermediate roller group of a flexographic, rotogravure, combining, spreading or offset machine to transfer ink in known manner onto a cylinder provided with said print characters (or images), said roller hence enabling said characters or images to be indirectly printed on a suitable support or substrate.

[0003] More in particular, as stated, a printing sleeve that is generally cylindrical in shape can be mounted onto a rotatable printing cylinder of a printing machine for printing images (or characters) onto the substrate. Most commercial printing machines have numerous printing cylinders and thus require numerous printing sleeves.

[0004] A variety of mechanisms can be used to mount the printing sleeve onto the printing cylinder. For instance, "air-mounting" is one common way of mounting a printing sleeve. Air-mounting generally refers to the placement of a printing sleeve onto a printing cylinder by supplying pressurized air between the sleeve and the cylinder. Typically, the printing sleeve has an inner surface diameter that is slightly smaller than the outer surface diameter of the printing cylinder. The difference in these diameters is a dimension known as the "interference fit". Thus, by applying pressurized air, the diameter of at least the inner surface of the printing sleeve can be slightly expanded so that the sleeve can be mounted onto and/or removed from a printing cylinder. Maintaining

the integrity of the interference fit is crucial to avoid slippage of the sleeve and resulting smearing or other unacceptable degradation of the image that is printed by the sleeve.

[0005] In some instances, an air-mountable printing sleeve can be formed from multiple concentric layers. In particular, most printing jobs involve an "image repeat", which is the circumferential length of the image that is to be printed one or more times on a substrate.

10 The circumference of a printing sleeve must be large enough to contain one or more image repeats. Moreover, different printing jobs may involve image repeats that differ in size, and consequently, different printing jobs may require printing sleeve repeats that also differ in size. For instance, a larger sleeve repeat size requires a printing sleeve with a larger circumferences or outer diameter for the same printing cylinder diameter.

[0006] To perform a job that requires a larger sleeve repeat size, the outer surface diameter of the printing sleeve must be large enough to yield the larger sleeve repeat size. Thus, printing sleeves resulting from multiple layers that increase the radial thickness of the sleeve are generally used to provide the necessary radial thickness. Specifically, the multi-layer printing sleeve has the

20 effect of increasing the outer diameter of the sleeve to provide a larger repeat size so that the sleeve can be mounted on a smaller diameter printing cylinder that is already available in inventory. The thicker the sleeves then the greater the inertial mass of the rotating sleeve and the greater the danger of slippage if the interference fit should become compromised during the life of the sleeve.

[0007] In printing it has always been a problem for the user to associate with each printing member information aimed at defining the physical characteristics (for example type, dimensions, characteristics of its constituent material or materials or of those of each cladding layer presented) or related to a previous use and such, for example, as to enable definition of a probable life span

30 or of the need to subject said member to a mechanical operation (for example grinding) which would prolong its useful life. In general, this information (particularly if related to the physical characteristics of the printing member) is provided on labels or punchings which are separated from said member immediately prior to its initial use or which become illegible after a few uses.

[0008] For example, one type of multi-layered sleeve that is currently used in the art includes an innermost core layer that is formed from wound fiberglass coated with epoxy resin. After a first run of fiberglass tape coated with epoxy resin has been wound around a cylindrically shaped forming mandrel, a paper label having a thickness that is both uniform throughout the label and less than one millimeter is laid on this first run and covered with a second run of fiberglass tape coated with epoxy resin. Such label is provided with information concerning the ultimate sleeve that is to be formed. So typically, the innermost core layer would not be formed until

it was known what type of sleeve was going to be built, so that the label could be created with the proper information and then embedded into the sleeve.

[0009] Subsequent runs of fiberglass tape coated with epoxy resin are successively wound around the length of the innermost core layer until the desired radial thickness of the innermost core layer has been attained for further processing. This desired radial thickness of this precursor stage of the innermost core layer will be larger than the ultimate desired radial thickness of the innermost core layer. In the further process of forming this innermost core, heat treatments that subject the innermost core layer to temperatures of about 90°C for about two hours are required. Thereafter, the innermost core layer of this multi-layered sleeve must undergo mechanical grinding and polishing to prepare it for the application of one of the subsequent additional layers that will compose the final multi-layered sleeve. The addition of these subsequent layers typically will also involve heat treatments and mechanical operations of grinding and polishing. Such treatments and operations can subject the sleeve to various expansions, compressions and twisting contortions.

[0010] In addition to the innermost core layer, the prior art multi-layered sleeve also can contain one or more layers that add thickness to the sleeve. To form these additional layers, materials such as rigid polyurethane foam or other forms of polyurethane (e.g., ISA-PUR 2330 and ISA-PUR 2340 which are sold by H.B. Fuller Austria, NOMEX® which is sold by DUPONT, and honeycomb structures) are utilized by the prior art sleeve. The thickness of such additional layers can vary depending on the particular image repeat utilized. In addition, other outer layers are also sometimes disposed on the outer surface of these layers, thereby further increasing the inertial mass of the sleeve and placing more importance on maintaining the interference fit of the sleeve.

[0011] Gravure and flexographic printing machines can produce images that have multiple different colors. In mounting each printing sleeve on its mandrel of the printing machine for such multi-color printing jobs, it is important that each printing sleeve be mounted in registry with each other printing sleeve so that the final printed image with all of the colors does not have one colored portion of the image bleeding into another colored portion of the image. Registration of each printing sleeve must be achieved not only circumferentially but also axially (side-to-side on the mandrel). In a conventional printing sleeve that carries a printing plate for use in creating an image on a conventional flexographic printing machine or in a conventional printing sleeve that is etched with an image for use in a gravure printing machine, the printing sleeve has a notch in the sleeve. The mandrel has a pin, and the printing sleeve is mounted on the mandrel with the pin surrounded by the notch in the printing sleeve. Registration of each printing sleeve is thus achieved by locating the sleeve's notch relative

to the mandrel's pin. The printing machine has an encoder on the servo-drive that indexes each mandrel so that the pin on mandrel points straight up at the 12 o'clock position at the beginning of each printing run of the machine. This is how the registration of the multi-color images is effected with conventional printing sleeves and printing machines.

[0012] However, as the sleeve is reused, the notch becomes wallowed out and cannot be reliably located 10 relative to the pin on the mandrel. Indeed, the pin of mandrel can be broken off with careless handling of the sleeves. Each of these conditions of sleeve wear and pin damage renders the conventional manner of registration of the printing sleeve unacceptably inaccurate. 15 Users of the printing sleeve must rely on less efficient methods for achieving the same registration of the sleeve on the mandrel of the printing machine. These less efficient methods can involve wastage of the underlying printing substrate during manual efforts to achieve 20 the desired registration of the multiple color job on the substrate.

[0013] There is therefore a need to provide a printing member, of which the information or data relevant to its use are always accessible to the user even after innumerable uses.

[0014] An object of the invention is therefore to provide an improved printing member.

[0015] Another object is to provide a printing member of the stated type which enables easy reading of these 30 data or information even after numerous years of use.

[0016] A further object is to provide a printing member of the stated type which also enables updating of the data relevant to its use, said updating allowing subsequent reading of all information concerning the previously used data regarding said member, of all information relative to mechanical operations which may have been carried out on said member (for example surface grinding), of all information relative to the wear of said member, and of all other information necessary and useful 35 in understanding its reliability and its possible life for further use.

[0017] A further object is to provide a method for obtaining the above cited printing member.

[0018] In particular, an object of the invention is to provide said method which is reliable and which can be carried out with the knowledge and means which do not negatively affect the manufacturing time and cost of said printing member.

[0019] Another object is to provide a method which 50 enables effecting the desired registration of said member on a printing machine for producing multi-color on the substrate that is being printed.

[0020] These and further objects which will be apparent to the expert of the art are attained by a printing 55 member and a method in accordance with the accompanying claims.

[0021] In particular, a printing sleeve of the present invention contains identification means such as, for ex-

ample, an RF transponder that includes an RFID chip that is embedded in a layer of the sleeve that is composed of a generally rigid and relatively expandable material. The invention also relates to a method of making said printing sleeves for use in flexographic or gravure printing applications.

[0022] In general, the printing sleeve can include a thin-walled sleeve that can stand alone or be used to form the innermost core layer of a multi-layer sleeve. In some embodiments, the thin-walled sleeve or innermost core layer of the printing sleeve desirably can be formed of an expandable, high rigidity material such as aramid fiber bonded with epoxy resin or polyester resin; reinforced polymeric material such as hardened glass fiber bonded with epoxy resin or polyester resin or similar known materials.

[0023] In accordance with the present invention, a thin-walled sleeve that is formed by winding successive runs of fiberglass tape that has been coated with epoxy resin and wound around a forming mandrel is provided with identification means, such as an RF transponder. A first run of fiberglass tape that has been coated with epoxy resin is helically wound around the length of a cylindrically shaped, rigid forming mandrel. An RF transponder is then placed on the outer surface of this first layer. Then, in accordance with the process of the present invention, a second layer of resin-coated fiberglass tape is wound around and covers the first layer of resin-coated fiberglass tape and around the transponder that is disposed on top of the first layer of resin-coated fiberglass tape. The transponder is thus disposed beneath at least a second layer of resin-imbued fiberglass tape that forms a thin-walled sleeve (and/or the innermost core of a sleeve) made in accordance with the present invention with but two runs of fiberglass tape. However, additional layers of resin-coated fiberglass tape desirably may be added on top of the second run until the desired thickness of resin-coated fiberglass has been attained for the particular sleeve that is desired.

[0024] In accordance with a further aspect of the present invention, the identification means or transponder in the thin-walled sleeve provides the possibility of an improved method of effecting the desired registration of the sleeves on a gravure or flexographic printing machine for producing multi-color images on the substrate that is being printed. This improved method is accomplished by providing the printing machine with detection means, such as a positioning scanner and desirably a positioning scanner at each printing station. The positioning scanner (or similar detection means) is electronically connected to the controller of the printing machine. The positioning scanner detects the precise location of the microprocessor in the transponder and provides this information to the controller of the printing machine. Using this information, the printing machine can index the position of each sleeve so that all of the sleeves are in common registration to produce the desired image on the substrate that is being printed. In this

way, all of the colors in the image are in proper registration from the very first image that is printed on the substrate by the machine. The improved method thereby eliminates the wastage of the substrate that occurs during manual registration with conventional sleeves.

[0025] The present invention will be better understood from the accompanying drawing, which is provided by way of non-limiting example and in which:

- 10 Figure 1 is a longitudinal side section through a printing member according to the invention;
- 15 Figure 2 is a section on the line 2-2 of Figure 1;
- 20 Figure 3 is a view similar to Figure 1, but of a first variant of the invention;
- 25 Figure 4 is a view similar to Figure 1, but of a second variant of the invention.

- 70 Figure 9 is the cross-sectional view identified in Fig. 8A by the arrows designated 9-9 and showing in chain-dashed line, bending of the transponder component;
- 75 Figure 10 schematically shows components of another embodiment of a sleeve made in accordance with the present invention; and
- 80 Figure 11 schematically shows another embodiment of an aspect of the present invention.

[0026] Repeat use of references characters in the present specification and drawings is intended to represent same or analogous features or elements of the invention.

[0027] With reference to Figures 1 and 2, these show a printing member defined by a printing cylinder 1 (roller or printing sleeve). Said cylinder comprises a body 2 having a longitudinal through hole 3 enabling the cylinder 1 to be arranged, in the manner known to the expert of the art and hence not described, on a known rotary support, for example of the radially expandable type, not

shown. The body 2 is of single layer type, i.e. it consists of a single metal, plastic or composite material (in that case, including binding resin).

[0028] The body 2 presents an outer surface 5 (carrying the print characters or images) distant from an inner wall 6 (bounding the through hole 3), between which there is a thickness 7. Finally the body 2 presents opposing end faces 8 and 9 perpendicular to the surfaces 5 and 6.

[0029] In the embodiment of the invention under examination, associated with the printing member defined by the cylinder 1 there are identification means defined by means 10 for identifying useful data related to at least one characteristic of the cylinder and to a physical value of this latter (for example, dimensions, characteristics of the constituent material of the cylinder 1, type of cylinder) or to a previous use of the cylinder (for example, the hours of previous use) or to a previous mechanical machining operation to which it has been subjected after its construction and, for example, after one or more uses. Preferably the data stored in the means 10 comprise a unique absolute code which, when displayed or transmitted remotely (by radio frequency), allows access (via suitable reading instruments defined hereinafter) to a plurality of the aforesaid characteristics. One or more characteristics of the cylinder 1 are identified via said identification means, said means consequently defining means for identifying the cylinder.

[0030] More specifically, the identification means 10 comprise a microprocessor unit or transponder 30 (see Fig. 8A and Fig. 8B) which is preferably powered from outside the cylinder 1 when the data stored in it are to be read. In this case, this power is supplied to the identification means 10 from outside the cylinder 1 and without contact with the means themselves. For this purpose, these latter are preferably of the known radio frequency identification system type and comprise, as will be explained below, the microprocessor unit in which the data identifying the cylinder 1 are stored and can also be read remotely by a radio frequency reading member 15 (of known type).

[0031] This member 15 is connected to a processor 16 (acting as recording means) by which the read data can be displayed (by monitor 17) to a user and possibly recorded on a suitable support (for example a compact disc - CD). The processor 16 can store information relative to the characteristics of the printing member or cylinder 1 and/or relative to dimensional and/or machining modifications which the cylinder has undergone. Consequently, the memory content of the recording means 16 can be updated by the user according to his own requirements: for example, by feeding data into it relative to the life of the product, grinding and/or wear data or any other data considered opportune by the user to facilitate the use of the sleeve.

[0032] In the example under examination, the identification means 10 are inserted into a seat 18 provided within the thickness 7 of the body 2 and, in the case of

Figures 1 and 2, reclosed by a suitable closure element 13; this latter can be of material of the same type as the constituent material of the body 2 or can be of composite material (for example glass fibre when the body 2 is of metal).

[0033] Figures 3 and 4 show variants of the invention. Figure 3 shows a cylinder 1 in which the seat 18 for the identification means 10 is provided in proximity to the lateral face 9 of the cylinder 1. The identification means 10 are hence located within the cylinder 1.

[0034] The identification means 10 of Figure 3 can also have the thickness of a label and be positioned directly on the face 9.

[0035] It should be noted that this position of the identification means 10 does not negatively affect the use of the printing member, nor can said means be damaged by this use because they are positioned on a side of said member which is not subjected to impacts or stresses during said use.

[0036] In contrast, in Figure 4 the cylinder 1 is a printing sleeve comprising, in known manner, two layers 1A and 1B which are torsionally rigid with each other and are defined by different materials (for example one layer is of glass fibre and relative binder, such as epoxy resin, while the other 1B is of polyurethane). In this case the identification means 10 are directly embedded in the polyurethane and are in a position such as to be identified on the surface 5 of the cylinder in order to enable them to be easily found.

[0037] As will be explained later, the layers of the cylinder or sleeve 1 can also be more than two or the cylinder (or sleeve) 1 can be a single layer or multi-layer support for a plate-carrying sleeve which is mounted (for example by compressed air deformation) on the surface 5 of the cylinder 1 (for example provided with through holes between the surfaces 5 and 6 to feed compressed air from the hole 3 to the surface 5 and hence mount said sleeve on it).

[0038] By using the microprocessor or chip containing a unique code for each cylinder, this code can be inserted into the body 2 of said cylinder, the code also being able to be read remotely via the reader 15.

[0039] Finally, in a further variant, the identification means 10 can also be associated with the exterior or interior of the cylinder 1 (for example on a lateral face 8 or 9 or in the hole 3 on the wall 6) instead of being inserted into its thickness 7. This variant is also to be considered as falling within the scope of the present document.

[0040] In a further variant, the recording means or processor 16 cooperate with separate specific identification members of the cylinder 1 defined by at least one code (alphanumeric, bar or other) associated with an outer surface, preferably with a lateral face 8 or 9, of the body 2. On reading this code (visually or by a suitable reader, for example by an optical reader), it can be fed into the processor 16 and act on its memory to insert data concerning the cylinder and related to its use. Said

memory already contains the cylinder data provided by the manufacturer, namely the dimensional, body material and other data. These data can hence be updated by the user.

[0041] More particularly, in the variant under examination, each cylinder 1 (roller or sleeve) produced is identified by a label for example with a bar code, positioned on the face 8 or 9 of the body 2.

[0042] A unique absolute code corresponding to the part serial number is reproduced on the identification means.

[0043] According to the invention as claimed, a file carrying all the production and technological characteristics of the individual part is provided on a computer support, associated with each code (stored in the microprocessor unit or carried by the identification means). This file can be updated each time the user acquires a new sleeve or roller, in order to create a complete database for the equipment available.

[0044] When the user uses the equipment, all the technical data of the roller or sleeve can be obtained by reading the code, updating the production runs and production times and any other information considered necessary and useful to file; a search can be made through the rollers/sleeves on the basis of production runs or working times or of any other parameter considered significant.

[0045] If the user has a radio frequency network system, communication between the reader and the roller/sleeve database can take place in real time, allowing direct dialogue between the operator working in the roller store and the database, with possible identification of the cylinder with the desired characteristics being sought. If the code is associated with the said microprocessor unit, the required cylinder can be very simply identified remotely.

[0046] If the user possesses a standard network system (via cable), the essential data of the sought roller (including its position in store) can be memorized in the reader, to then precisely identify it by code correspondence.

[0047] In both cases the data relative to a cylinder/sleeve can always be updated via a fixed station (processor 16) which dialogues with the database.

[0048] The invention provides a printing member of the aforesaid type with which useful information for its use is always associated, as heretofore described. This information is advantageously and preferably updatable.

[0049] Reference now will be made in detail to the embodiments of the invention shown in figures 5 to 11, one or more examples of which are set forth below. Each example is provided by way of explanation of the invention, not limitation of the invention. In fact, it will be apparent to those skilled in the art that various modifications and variations can be made in the present invention without departing from the scope or spirit of the invention. For instance, features illustrated or described

as part of one embodiment, can be used on another embodiment to yield a still further embodiment. Thus, it is intended that the present invention cover such modifications and variations and their equivalents.

[0050] In general, as stated, the present invention is also directed to an improved method of making printing sleeves for use in flexographic or gravure printing and indirect or offset printing.

[0051] Many printing sleeves are based on the formation of a thin-walled substrate that either stands alone as the printing sleeve itself or forms the innermost core layer of a multi-layer printing sleeve. Formation of a thin-walled printing sleeve 1, which also can become the innermost core layer 1 of a multi-layer sleeve, in accordance with the present invention now will be described with reference initially to Fig. 5. For the sake of simplicity, the description will refer to the formation of a stand-alone thin-walled sleeve 1 such as shown in Fig. 6D. But the description is equally applicable to the formation of an innermost core layer 1 of a multi-layer sleeve 40 such as shown in Fig. 7 unless otherwise indicated.

[0052] As schematically shown in Fig. 6C, a thin-walled sleeve 1 is formed from wound fiberglass tape that has been coated with epoxy resin and wound around a forming mandrel 19.

[0053] In general, any of a variety of materials used in forming printing sleeves can be utilized to form the thin-walled sleeve 1 that also can become a core layer 1. In some embodiments, the thin-walled sleeve (or core layer) 1 is formed of an expandable, high rigidity material. Such materials are expandable so that the thin-walled sleeve 1 can be repeatedly expanded and contracted without adverse consequences. Such non-destructive expansion and contraction permits the inner surface of the sleeve 1 to form an interference fit with the outer surface of a rotary support. The degree of permitted expansion and contraction need not be so large as to be detectable by the naked eye.

[0054] Some examples of compositions that are suitable for composing the thin-walled sleeve 1 include, but are not limited to, aramid fiber bonded with epoxy resin or polyester resin; reinforced polymeric material such as hardened glass fiber bonded with epoxy resin or polyester resin, the latter two also known as fiberglass reinforced epoxy resin or fiberglass reinforced polyester; DUPONT® MYLAR® or tri-laminate KEVLAR® that may optionally be reinforced with a resin, such as epoxy resin or polyester resin; carbon-reinforced epoxy resin; and the like.

[0055] Moreover, the radial thickness of the thin-walled sleeve 1 also can vary, depending on the desired application. For instance, in some embodiments, the thin-walled sleeve 1 can have a thickness between about 0.020 to about 0.100 inches (0,0508 - 0,254 cm), with the larger thickness being used for sleeves with greater diameters and/or axial length. For example, in one particular embodiment, the thin-walled sleeve 1 is made from wound fiberglass that is coated with epoxy

resin having a thickness of 0.040 inches (0,1016 cm). [0056] In accordance with the present invention and as schematically shown in Fig. 5, a first run 21 of fiberglass tape 20 that has been coated with epoxy resin 25 has been helically wound around the length of a cylindrically shaped, rigid forming mandrel 19 with each successive wrapping positioned so as to slightly overlap the prior adjacent wrapping. The outer surface of the mandrel 19 can be shaped as a right cylinder or can be tapered, depending on the desired shape of the innermost surface of the thin-walled sleeve 1.

[0057] As schematically shown by the curved arrow designated 23 in Fig. 5, the forming mandrel 19 is rotated to wind a first layer 21 of fiberglass tape 20 that has been passed through a vessel 24 holding a bath of epoxy resin 25. During the rotation of the mandrel 19, the mandrel is translated back and forth along the axis of rotation of the mandrel. This reciprocating axial translation of the mandrel 19 is schematically indicated in Fig. 5 by the double-headed arrow designated 26 and results in a helical, slightly overlapped winding pattern, with the pitch determined by the speed of rotation and the speed of translation.

[0058] A phantom representation of the mandrel 19 covered by the first layer of resin-imbued fiberglass tape 21 is shown by the chain-dashed outline toward the left of the view shown in Fig. 5. The phantom representation illustrates the mandrel 19 at one extreme position of the mandrel's axial translation.

[0059] As shown in Fig. 6A, in accordance with the process of the present invention, after an initial layer 21 of fiberglass tape 20 has been wound around the mandrel 19, a transponder 30 (defining an identification means) is placed on the outer surface of this first layer 21 that is to form the thin-walled sleeve 1. Because of the tackiness of the epoxy resin, the transponder 30 will adhere to this outer surface of the first layer 21 of resin-imbued fiberglass tape 20.

[0060] Then, as shown in Fig. 6C and in accordance with the process of the present invention, a second layer 22 of resin-coated fiberglass tape 20 is wound around and covers the first layer of resin-coated fiberglass tape and around the transponder 30 that is disposed on top of the first layer of resin-coated fiberglass tape. As shown in Fig. 6C, the dashed lines schematically indicate that the transponder 30 is disposed beneath at least a second layer 22 of resin-imbued fiberglass tape that forms a thin-walled sleeve 1 (and/or the innermost core 1 of a sleeve) that is made in accordance with the present invention with only two runs of fiberglass tape 20. Desirably, additional layers of resin-coated fiberglass tape may be added on top of the second run 22 until the desired thickness of resin-coated fiberglass has been attained for the particular application.

[0061] In accordance with the present invention, the thickest portion of the transponder 30 should be less than about one millimeter thick, which is measured in the radial direction when the transponder 30 is posi-

tioned on the first run 21 of resin-coated fiberglass. In this way, the presence of the transponder 30 between the first and second layers of the thin-walled sleeve 1 does not result in any detectable degradation of the performance of the finished thin-walled sleeve 1. For example, there is no functionally appreciable degradation in the interference fit between the inner surface 6 (Fig. 6D) of the sleeve 1 and the exterior surface of the rotary support on which the sleeve becomes mounted during

10 operation of the printing machine. Desirably, the thickest portion of the transponder should be less than about one half millimeter thick.

[0062] As used herein and shown in Figs. 8A, 8B and 15 9, the transponder 30 is part of what are known as Automatic Identification and Data Capture (AIDC) products. Transponder 30 can include a radio frequency (RF) device, which in one exemplary embodiment may correspond to an RFID transponder (or RFID tag), such as a TAG-IT™ HF-I transponder inlay offered for sale by 20 Texas Instruments of Dallas, Texas. As shown in Figs. 8A, 8B and 9, the RF device may be made up of at least a silicon chip 32 and signaling components for relaying RF signals to a remote location. The silicon chip 32 can include a memory device, which desirably may be a digital 25 memory device. The RF device also comprises an antenna 34.

[0063] The RF devices in accordance with the present technology may be either active devices, which transmit signals directly to a scanner at a remote location, or passive 30 devices, which reflect or backscatter RF transmission from a separate interrogator or reader device. The transponder 30 can provide location information to a positioning scanner that enables the positioning scanner to determine the position of the transponder relative to

35 the positioning scanner and provide this positioning information to a microprocessor or machine controller of the printing machine. The RF signals relayed by the RF device of transponder 30 may in some embodiments be characterized by selected frequency levels in the UHF band of 300 MHz to 3000 MHz. Such RF signals may include a variety of predetermined information, including various preprogrammed identification information for a sleeve structure, as mentioned below in more detail. The RF device also may desirably include an application-specific integrated circuit (ASIC) for further customizing the identification information available to a user.

[0064] Additional sensor elements, such as those suitable for monitoring the temperature, pressure, and other conditions within a sleeve, may be integrated with 40 or coupled to the RF device of the transponder 30 so that measurements of a sleeve's physical conditions also may be included in the RF signals communicated by the RF device.

[0065] As schematically indicated by the double-headed arrow designated 33a in Fig. 8A, the length of 45 a generally rectangular-shaped transponder 30 can be about 76 millimeters. As indicated by the double-headed arrow designated 33b in Fig. 8A, the width of such a

transponder 30 can be on the order of 48 millimeters. As indicated by the double-headed arrow designated 33c in Fig. 8A, the width of the antenna 34 of the transponder can be on the order of 45 millimeters. As indicated by the double-headed arrow designated 33d in Fig. 8A, the center point of the memory chip 32 of the transponder 30 can be positioned about 23.4 millimeters from the longer side of the transponder. Similarly, the distance of the center point of the memory chip 32 can be disposed about 17.3 millimeters from the shorter side of the transponder 30 depicted in Fig. 8A. This configuration of the transponder 30 is merely exemplary and not intended to be restrictive of the different configurations that could be used in accordance with the present invention.

[0066] However, in accordance with the present invention, the transponder's thickness, which is measured in the radial direction when the transponder 30 is positioned on the first run 21 of resin-coated fiberglass, should be less than about one millimeter and more preferably less than about one half millimeter. As shown in Fig. 9, the thickness of the transponder 30 is not uniform throughout the entire transponder. As shown in Fig. 5, the thickness of the transponder's memory chip 32 depicted in Fig. 4A is about 0.355 millimeters, and the thickness of the antenna 34 is about 0.085 millimeters.

[0067] The antenna size of this embodiment of the transponder 30 depicted in Fig. 8A can be about 45 millimeters by 76 millimeters. The antenna 34 desirably is formed of a conductive material such as aluminum. The substrate of the transponder desirably can be formed of polyethylenetherephthalate (PET) and thus is flexible to a bending radius that desirably is about eighteen (18) millimeters.

[0068] The memory chip 32 desirably can be provided with a programmable memory that has 2000 bits organized in 64 by 34 bit blocks. The supported standard of the transponder 30 can be ISO 15693-2,3 with a recommended operating frequency of 13.56 megahertz.

[0069] Since the antenna 34 of the transponder 30 surrounds the memory chip 32, it is not important how the antenna 34 is oriented on the surface of the first layer 21 of fiberglass tape imbued with resin.

[0070] The transponder 30 has the ability to receive information from the sleeve manufacturer as well as from the client that purchases the sleeve to use on the printing machine. Users of the sleeve find it desirable to write to the transponder 30 such information as how long the sleeve has been run and accordingly the number of feet with each use, the image that was mounted on the sleeve 1, the roll of the printing machine that the sleeve was mounted on, and any other particularities that are characteristic of the sleeve that might help the user save time in mounting the sleeve on the machine and preparing the sleeve for the printing process. Other information that is useful to write to the transponder 30 of the sleeve could include the job on which the sleeve was used and any problems that were encountered during the last us-

age of the sleeve.

[0071] A generally square-shaped transponder 30 is depicted schematically in Fig. 8B and is not uniformly the same thickness throughout the entire transponder, but does not exceed about one half millimeter in thickness at any point in the transponder. As indicated by the double-headed arrow designated 33b in Fig. 8B, the width of such a transponder 30 can be on the order of 48 millimeters, and the length is the same. As indicated by the double-headed arrow designated 33c in Fig. 8B, the width of the antenna 34 of the transponder can be on the order of 45 millimeters. As indicated by the double-headed arrow designated 33d in Fig. 8B, the center point of the memory chip 32 of the transponder 30 can be positioned about 23.4 millimeters from the side of the transponder. Similarly, the distance of the center point of the memory chip can be disposed about 17.3 millimeters from the front of the transponder 30 depicted in Fig. 8B. The substrate of the square-shaped transponder desirably can be formed of polyethylenetherephthalate (PET) and thus is flexible to a bending radius that desirably is about eighteen (18) millimeters. Again, this configuration is merely exemplary and not intended to be restrictive of the different configurations that could be used in accordance with the present invention.

[0072] Subsequent runs of slightly overlapped fiberglass tape coated with epoxy resin are successively wound around the length of the mandrel after the second run 22 until the desired radial thickness of the thin-walled sleeve 1 has been attained for further processing. This desired radial thickness of this precursor stage of the thin-walled sleeve 1 will be larger than the ultimate desired radial thickness of the final sleeve 1 or innermost core layer 1. In the further process of forming this thin-walled sleeve 1, heat treatments that subject the sleeve to temperatures of about 90°C for about two hours are required. Thereafter, the thin-walled sleeve 1 must be finished by undergoing mechanical grinding and polishing. As shown in Fig. 6D, the thin-walled sleeve 1 that results from the process of the present invention will include an RF transponder 30 that will be embedded into the final thin-walled sleeve 1. Moreover, the thin-walled sleeve 1 can also be made in a manner similar to the printing sleeves in U.S. Patent No. 4,144,812 to Julian or 4,903,597 to Hoage, et al..

[0073] It has been found that the bending of the transponders 30 during manufacture of the sleeve and during subsequent use of the sleeve does not adversely affect the performance of the transponder. Additionally, the heat treatments that must be applied to the sleeve during manufacture of the sleeve also do not degrade the performance of the transponder 30 in the final manufactured sleeve. Moreover, notwithstanding that the thickness of the transponder 30 varies between different locations on the transponder and that the transponder is disposed only one very thin layer of fiberglass tape removed from the inside surface 6 (see Fig. 6D) of the sleeve 1, there is no functionally appreciable degrada-

tion in the interference fit between the inner surface of the sleeve and the exterior surface of the rotary support on which the sleeve becomes mounted during operation of the printing machine.

[0074] As shown in Fig. 7, a thin-walled sleeve 1 such as shown in Fig. 6D can be used as the innermost core layer 1 of a multi-layered sleeve 40 that can have several additional layers 41, 42, which are schematically indicated by the dashed lines and are shown partially cut away. Though only two additional layers are depicted in Fig. 7, more than two additional layers can be used.

[0075] In a multi-layered sleeve 40 such as shown in Fig. 7, the finishing of the innermost core layer 1 such as shown in Fig. 6D will prepare the exterior surface 5 (Fig. 6D) of the innermost core layer 1 for the application of one of the subsequent additional layers (such as layers 41, 42 if only two are involved) that will compose the final multi-layered sleeve 40. The formation of these additional layers also will typically involve heat treatments and mechanical operations of grinding and polishing. Such treatments and operations also can subject the multi-layer sleeve 40 to various expansions, compressions and twisting contortions.

[0076] One or more additional layer(s) can be used to add further thickness to the multi-layered sleeve 40 and/or as a cover layer for the sleeve 40. In general, any number, size, shape, and/or type of additional layers can be used in the present invention, so long as the resulting printing sleeve can be air-mounted onto a printing cylinder; sleeves which can be used in this invention are described in the following US patents: Nos. 5,782,181; 5,735,206; 5,819,657; 6,691,614; and 6,688,226.

[0077] One such additional layer can be formed from a generally rigid, relatively expandable material. As used herein, the phrase "rigid" refers to a material having a certain Shore hardness. In some embodiments, for example, the additional layer can be made from a material having a Shore D hardness of about 20 to about 85, and in some embodiments, from about 45 to about 50. In one particular embodiment, for example, the additional layer can contain a polyurethane material having a Shore D hardness between about 45 to about 50. One such polyurethane material may be obtained from H.B. Fuller Austria under the tradename ISA-PUR 2330.

[0078] Besides being generally rigid, the additional layer, as stated above, can also be relatively expandable. As used herein, the term "expandable" refers to a material that can expand a certain radial distance upon the application of air at a certain pressure. For example, at air pressures between about 80 to about 90 psi, the printing sleeves typically expand in a radial direction between about 0.0015 to about 0.0045 inches (0,00381 - 0,01143 cm), and in some embodiments, between about 0.0025 to about 0.0035 inches (0,00635 - 0,00889 cm). For example, in one embodiment, a printing sleeve having a diameter less than 7 inches (17,78 cm) expands, in a radial direction, about 0.0025 inches (0,00635 cm). Moreover, in another embodiment, a printing sleeve

having an inner diameter greater than 7 inches (17,78 cm) expands, in a radial direction, about 0.0035 inches (0,00889 cm). The thickness of this additional layer can generally vary. In most embodiments, for example, the thickness of this additional layer is between about 0.125 to about 1.50 inches (0,3175 - 3,81 cm), and in some embodiments, between about 0.125 inches (0,3175 cm) to about 1.00 inches (2,54 cm).

[0079] Some suitable materials that can be utilized in forming other additional outer layers include, but are not limited to, aramid fiber bonded with epoxy resin or polyester resin; reinforced polymeric material such as hardened glass fiber bonded with epoxy resin or polyester resin, the latter two also known as fiberglass reinforced

10 epoxy resin or fiberglass reinforced polyester; DUPONT® MYLAR® or tri-laminate KEVLAR®; a polyurethane material (e.g., ISA-PUR 2330 or ISA-PUR 2340 from H.B. Fuller Austria under the tradename ISA-PUR 2330); elastomeric rubber materials; elastomeric polyurethane materials; polyurethane expanded foam; open cell polyurethane foam; nickel; copper; carbon-reinforced epoxy resin; and the like. In some em-

15 bodiments, a metal outer layer, such as an aluminum extruded layer, can also be included.

[0080] As schematically shown in Fig. 10, an alternative embodiment of a sleeve 50 made in accordance with the present invention can include an elongated piezoelectric crystal 51 that acts as a transducer that supplies an electrical signal to the memory chip of the transponder 30 (or identification means). During the man-

20 ufacturing process, the crystal 51 is laid on the first run 21 of fiberglass tape 20 along with the transponder 30. The crystal 51 is electrically connected to the transpon-

25 der 30, which may be provided with an analog-to-digital converter and a digital-to-analog converter, either by hardware or software. In this way, the transponder 30 can be used to record for later download and/or transmit in real time, pressures and the type of bending stresses that the sleeve 50 is undergoing during usage. Such in-

30 formation will aid in the diagnosis of any problems with the performance of the sleeve 50 during use on the printing machine. Arrangements like sleeve 50 shown in Fig. 6 also can be used in prototype test sleeves that are built during development of new sleeve products.

[0081] In accordance with a further aspect of the present invention, the transponder in the thin-walled sleeve enables an improved method of effecting the desired registration of the sleeves on a gravure or flexographic printing machine for producing multi-color images on the substrate that is being printed. As schemati-

35 cally shown in Fig. 11, a thin-walled sleeve 1 made in accordance with the present invention is mounted on a rotary support or mandrel 61 of a printing machine that is schematically designated by the numeral 60. The sleeve 1 carries a printing plate 45 shown in phantom (dashed line) with an image 46 (or character) that is also shown in phantom.

[0082] As schematically shown in Fig. 11, the printing

machine 60 is provided with a positioning scanner 62 that is mounted at the printing station of the mandrel 61. Desirably, a separate positioning scanner 62 will be provided at each printing station of the machine 60. As schematically shown by the line designated 64, the positioning scanner 62 is electronically connected to the controller 63 of the printing machine 60. As schematically shown by the diverging lines designated 65, the positioning scanner 62 detects the precise location of the microprocessor chip 32 in the transponder 30 and provides this information to the controller 63 of the printing machine 60. Using this information, the printing machine 60 can index the position of each sleeve so that all of the sleeves at all of the printing stations of the machine are in common registration to produce the desired image on the substrate that is being printed. In this way, all of the colors in the image (or the characters) are in proper registration from the very first image that is printed on the substrate by the machine. The improved method thereby eliminates the wastage of the substrate that occurs during manual registration of conventional sleeves.

[0083] As shown in Fig. 7B, after an initial layer 21 of fiberglass tape 20 has been wound around the mandrel 19, a label 31 can be placed on the outer surface of this first layer 21 that is to form the final thin-walled sleeve 1. The label 31, which desirably is formed of paper that carries data expressed in ink markings, also can be covered with a second run of fiberglass tape coated with epoxy resin. Thus, the label 31 also can be embedded within the thin-walled sleeve 1 as the different layers of fiberglass tape are wound around the prior layers of fiberglass tape. Indeed, as shown in Fig. 6B, such a label 31 can be disposed between the same two layers that sandwich the transponder 30. Alternatively, such a label 31 can be disposed between different layers than the ones that sandwich the transponder 30. The label 31 can include a machine-readable bar code or information that is readable by the naked human eye and readily comprehensible by the human reader, as desired. Such label has a thickness of less than one millimeter and typically is provided with information concerning the ultimate sleeve that is to be formed.

[0084] In accordance with the present invention, because of the presence of the transponder 30 that can receive and store information that can be retrieved subsequently, the innermost core layer 1 of a multi-layer sleeve can be formed before it is known what type of sleeve is going to be built, and the label 31 could be created with generic information that is not particular to any specific customer or type of sleeve or merely provided with a trademark. In an alternative case such as shown in Fig. 6D, the label 31 can be omitted altogether.

[0085] The improved method of the present invention equally applies to the method of making a sleeve for an indirect or offset printing machine and in particular to an offset blanket cylinder. As is well known, in an offset machine or a lithographic rotary machine with indirect print-

ing and comprising three main cylinders, a second, subsidiary cylinder (or blanket cylinder) receives the inked data (characters or images) to be printed (i.e., "the impression") from a first cylinder and transfers the data to a substrate or web of paper or other material (for example plastic), that is interposed between the blanket cylinder and a third cylinder or pressing (or printing) cylinder. After transforming the inked data to the substrate, the surface of the blanket cylinder passes through a bath of solvents that wash the residual ink from the surface of the blanket cylinder.

[0086] Although various embodiments of the invention have been described using specific terms, devices, and methods, such description is for illustrative purposes only. The words used are words of description rather than of limitation. It is to be understood that changes and variations may be made by those of ordinary skill in the art without departing from the spirit or scope of the present invention, which is set forth in the following claims. In addition, it should be understood that aspects of the various embodiments may be interchanged both in whole or in part. Therefore, the spirit and scope of the appended claims should not be limited to the description of the preferred versions contained therein.

25

Claims

1. A printing member (1) such as a printing cylinder, for example an at least partly metal cylinder, or a sleeve to be mounted on a mandrel rotating about its axis, said printing member (1) comprising a body (2) having a thickness (7) and a through hole (3) bounded by an inner surface (6) of said body, said body (2) being formed as a single layer or with a plurality of layers (1A, 1B) torsionally rigid with each other and defining said thickness (7), the body (2) having an outer surface (5) and lateral faces (8, 9), **characterised by** comprising identification means (10) arranged to cooperate operationally with recording means (16) which are updatable after each use of the printing member (1), and are able to store data relating to at least one characteristic of said member (1) useful for its use.
2. A printing member as claimed in claim 1, **characterised in that** the characteristic stored by the recording means (16) is at least one of the following: at least a characteristic related to a physical value of the printing member (1), at least a characteristic related to a previous use of said member (1), at least a characteristic concerning a mechanical machining operation to which this latter has been subjected after its construction.
3. A printing member as claimed in claim 2, **characterised in that** the characteristic related to a physical value relates to at least one of the following el-

ements: dimensions of the printing member (1), characteristics of the constituent material thereof, wear of said member (1) and its type of use, **in that** the characteristic related to a previous use regards the hours of this previous use of the printing member, and **in that** the characteristic concerning a machining operation relates to surface machining of said member (1).

4. A printing member as claimed in claim 1, **characterised in that** the identification means (10) are inserted into the body (2) of said printing member (1).
5. A printing member as claimed in claim 4, **characterised in that** the identification means (10) are inserted into a seat (18) provided within the thickness (7) of its body (2).
6. A printing member as claimed in claim 4, **characterised in that** the identification means (10) are located between two superimposed layers of the body (2) of the printing member (1).
7. A printing member as claimed in claim 1, **characterised in that** the identification means (10) are associated with a visible surface of the body (2) of the printing member, said visible surface being preferably a lateral face (8, 9) of said body.
8. A printing member as claimed in claim 1, **characterised in that** the identification means (10) are associated with the inner surface (6) of the body (2) of said printing member (1).
9. A printing member as claimed in claim 1, **characterised in that** the identification means (10) comprise a microprocessor unit.
10. A printing member as claimed in claim 14, **characterised in that** the microprocessor unit is of the radio frequency identification system type or RF device (30).
11. A printing member as claimed in claim 10, **characterised in that** the RF device (30) comprises at least a chip (32) and an antenna (34), the antenna (34) surrounding the chip (32).
12. A printing member as claimed in claim 10, **characterised in that** the chip (32) and the antenna are supported by a flexible substrate.
13. A printing member as claimed in claim 10, **characterised in that** the RF device is an active device and transmits signals to remote detection means, said means being at least a scanner (62).
14. A printing member as claimed in claim 13, **characterised in that** the scanner is a positioning scanner (62) of a printing machine.
15. A printing member as claimed in claim 10, **characterised in that** the RF device is a passive device which reflects or backscatters RF transmission from a separate interrogator or reader device.
16. A printing member as claimed in claim 10, **characterised in that** the RF device is a RFID transponder or RFID tag.
17. A printing member as claimed in claim 10, **characterised in that** the RF device includes an application-specific integrated circuit (ASIC) for further customizing the identification information available to a user.
18. A printing member as claimed in claim 10, **characterised in that** the RF device has a thickness less than about one millimeter and more preferably less than about one half millimeter.
19. A printing member as claimed in claim 10, **characterised in that** the RF device comprises additional sensor elements, such as those suitable for monitoring the temperature, pressure, and other conditions within a sleeve.
20. A printing member as claimed in claim 15, **characterised in that** the RF device cooperates with an elongated transductor (51) located along a longitudinal axis of the printing member.
21. A printing member as claimed in claim 1, **characterised in that** the identification means (10) comprise an identifying label for said member (1) which is secured to this latter and arranged to uniquely cooperate with the updatable recording means (16) for the data relative to said member, said label carrying a code, preferably a bar code.
22. A printing member as claimed in claim 1, **characterised in that** the recording means (16) are an electronic processor.
23. A printing member as claimed in claim 1, **characterised in that** its body (2) is at least partly of metal.
24. A printing member as claimed in claim 1, **characterised in that** its body (2) is of composite material such as glass fibre, carbon fibre or aramid fibre and relative binding material such as epoxy resin.
25. A printing member as claimed in claim 1, **characterised in that** its body (2) is layered and at least one layer is of expanded polyurethane, the latter being interposed between two layers of composite

material.

26. A method of embedding identification means (10),
in particular an RF assembly (30) during formation
of a printing sleeve (1), comprising:

5

- a) dipping fiberglass tape (20) in a resin bath (25);
- b) starting near a first end of a cylindrical mandrel (19), winding the dipped tape (20) in a helical fashion around the cylindrical mandrel (19)
to form a first layer (21) of the dipped tape (20)
covering the mandrel (19) for a first predetermined length; **characterised by** the following
steps:
- c) laying the RF transponder (30) on the first layer (21) of the dipped tape (20) that covers the mandrel (19);
- d) winding the dipped tape (20) in a helical fashion around the cylindrical mandrel until a second layer (22) of the dipped tape (20) covers the RF transponder (30) and covers a second predetermined length of the first layer (21).

10

15

20

27. A method as defined in claim 26, further comprising applying additional layers of the dipped tape (20) to form a precursor sleeve and thereafter heat treating the precursor sleeve and thereafter finishing the precursor sleeve to form a thin-walled sleeve.

25

30

28. A method as defined in claim 27, further comprising forming a multi-layer sleeve by applying at least a first additional layer to the thin-walled sleeve.

35

29. A method as defined in claim 28, further comprising forming a multi-layer sleeve by applying at least a second additional layer to the first additional layer that was applied to the thin-walled sleeve.

35

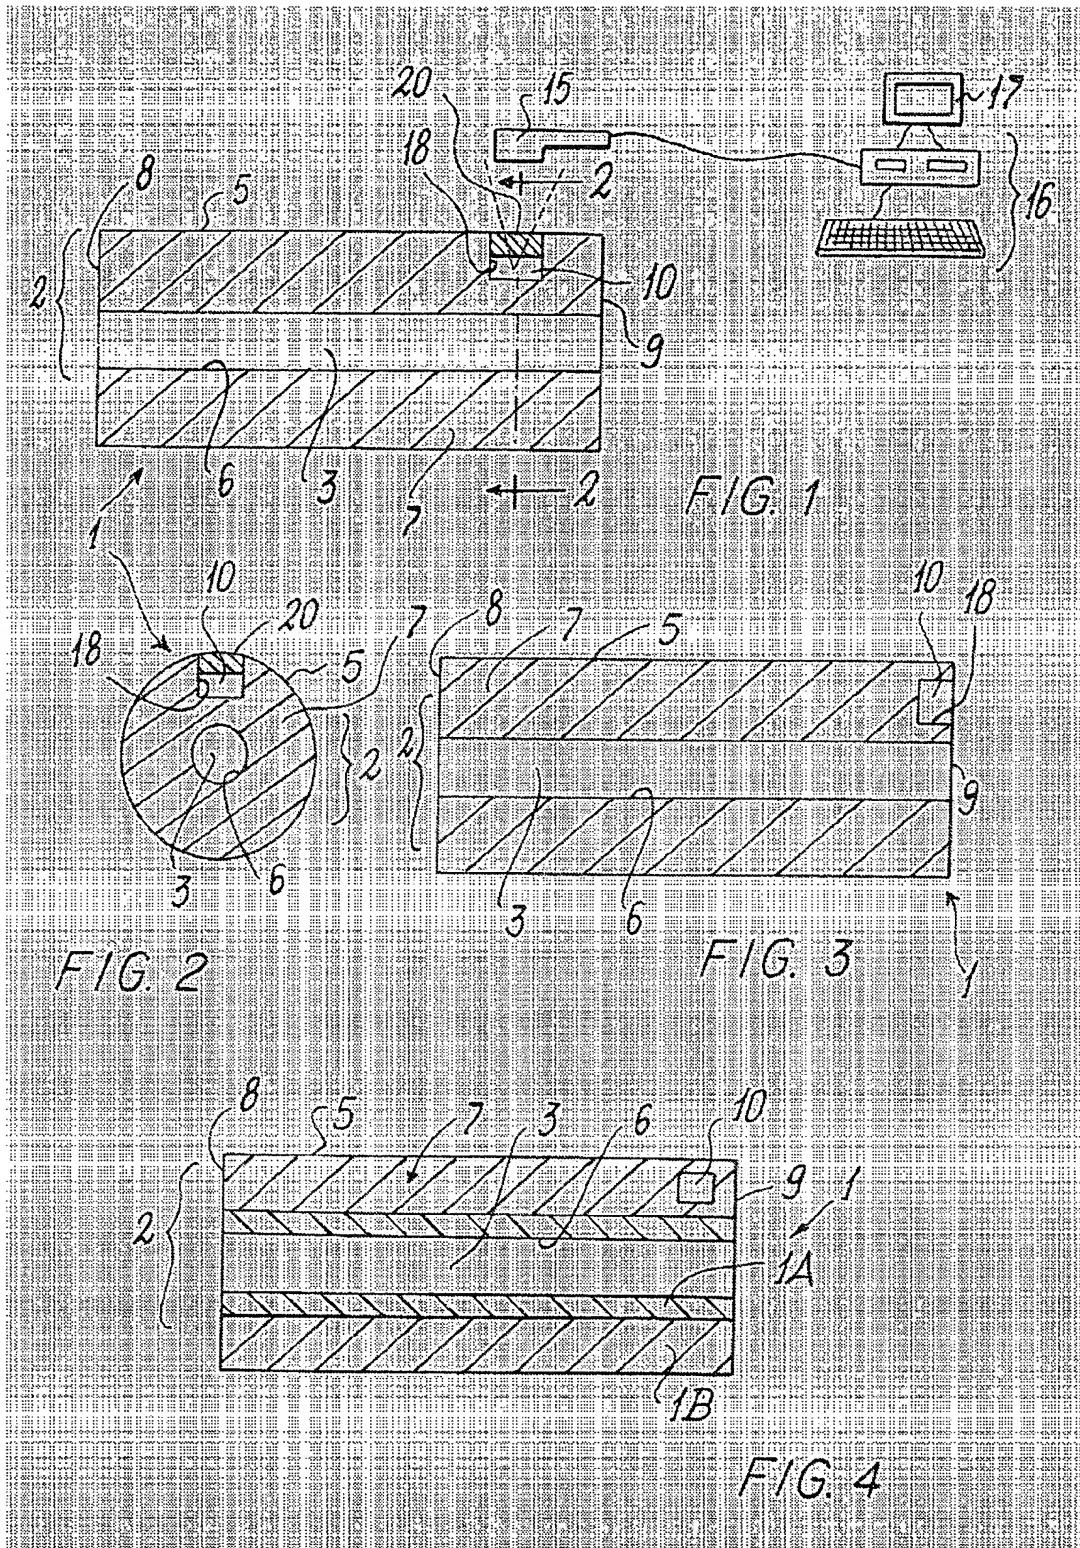

30. A method as defined in claim 26, wherein a piezoelectric crystal (51) is connected electrically to the transponder (30) before winding the second layer (22) of dipped tape (20).
